

EVALUATION OF COMPETENCES POSSESSED BY SECURITY GUARDS EMPLOYED BY PRIVATE SECURITY

Stanislav Dadelo

ABSTRACT

The present article provides research data elicited from the leading managers (experts) of a private security concerning the evaluation of competences. The article offers classifications of the security guard competences and an algorithm for the computation of the level of their

importance. The findings show the distribution of competences falling into the categories of very important, important, and slightly important competences. Investigation into the correlation of findings indicates that the system for the evaluation of security guards competences ought to be characterised by a larger number of indices under evaluation.

KEYWORDS

internal evaluation, external evaluation

INTRODUCTION

EU private security sector employs millions of people, and this index rises steadily¹. Private security is a dominant factor of public security in the world, (the ratio of the private security sector employees to the governmental criminal service officers is about 2:1)². The tendencies of economic development foresee the growth of public threats and dangers³ as well as further development of private security. It is envisaged that over the coming 10 years the demand for working places in the USA private security sector will increase by 15% which is a much higher growth rate compared to the overall rise in working places in the total USA economy⁴.

Specific personnel management targets are formed in the security. Personnel selection and deployment at essential positions (selection) is appraised as a key factor affecting the security, stability and development of performance in business⁵. The personnel selection procedure concentrates on the study and evaluation of potentialities, competences and personal properties of candidates (human recourse). The security staff evaluation procedure demands identification and determination of values of weights of specific personal criteria required for occupying a definite position at work⁶. It is necessary to create universal algorithms for the

staff selection⁷. The currently operated personnel selection and evaluation systems are usually oriented to the reduction of business costs in order to optimize the planning of the demand for and the distribution of staff⁸. In the area of security this idea is implemented by classifying objects by their importance and risk as well as by identifying the staff selection criteria and determining their values. Relatively, the private security objects may be divided by security measures applied by them and the character of values entrusted to them: 1) observation; 2) non-armed guard; 3) armed guard; 4) personal guard⁹. An **urgent** task is to search for factors affecting the efficaciousness of security guards' professional performance. Identification of the values of weights of security guards' professional performance will serve as a basis for the optimization of employee evaluation and selection for carrying out tasks differing in terms of complexity and character, and for the generation of algorithms of the security guard selection procedures¹⁰. The process of private security staff selection ought to direct the evaluation of properties possessed by a security guard in two directions: external (evaluation by a direct superior) and internal (personal abilities and properties)¹¹. This process requires defining key competences of security workers and rating them depending on work aims. However, evaluation and decisions taken by a single person are less correct than those made collectively with the difference between the two amounting to 26%¹² and finding mathematically evaluated existing

weighting factors, because there is no method able to effectively assess the optimal combination of the dynamic properties of the system. It is clear that all players rated indicators have different effects on their performance. However, there are no objective methods; arrows of weight and expert assessment of the methods used can be considered subjective but based on objective methods. The **purpose** of study: determination of the values of weights and importance of competences possessed by private security staff.

METHODS

Research subject: Leader managers (experts) of G4S Lietuva (n=22) with not less than 10 years of service at private security structures involving execution and organisation of security.

Research object:

Security guards competences. Description of the notion of competences depends on the area, subject and specific character of research¹³. When appraising professional performance of a security guard, competences ought to be understood as external and internal factors affecting the efficaciousness of professional performance, and generated by the security guard's personality.

Security guards internal evaluation (x): the data received were classified into six groups of competences (variables) regarding the features analysed¹⁴ (Table 1):

1. Theoretical and practical preparation (x_1): knowledge, skills, abilities, practical experience—acquired throughout life;
2. Professional activity (x_2): carrying out required tasks;
3. Mental qualities (x_3): individual psychical qualities vital for performance of professional activities;
4. Physical development (x_4): morphological indications of a body;
5. Motor abilities (x_5): personal physical conditions allowing carrying out physical

tasks at work or home, during leisure, and reflecting the level of physical qualities;

6. Fighting efficiency (x_6): a set of physical and mental qualities influencing the ability to effectively carry out actions fighting an adversary in direct contact.

Security guards external evaluation (y): factors selected based on A. Sakalas (2003) modified methodology (Table 1)¹⁵. They have been assessed on nine criteria that could affect security guards professional competences:

1. Specialty knowledge, professionalism (y_1): versatility, knowledge about their and related occupations;
2. Diligence and positive attitude to work (y_2): activeness, responsibility, discipline, zeal, vocation to work;
3. Behaviour with colleagues and supervisors (y_3): the ability to cooperate and work in a team;
4. Reliability at work (y_4): ability and willingness to perform tasks independently;
5. Quality of work (y_5): the ability to avoid mistakes;
6. Workload performance (y_6): the ability to carry out the maximum amount of work;
7. Image (y_7): the self-representational skills (exterior, posture, language culture);
8. Development rate (y_8): the ability to quickly adapt to new requirements and new working conditions;
9. Being promising (y_9): potential for career.

Determination of criteria weights by expert.

The expert judgment method was used to determine criteria weights. The algorithm of criteria weight establishment and process of calculation¹⁶ is presented in Table 2. Once calculations were performed, criteria weights were established (Table 1).

Determination of statistical relation between variables (expert judgement).

In order to find relations between variables Pearson linear correlation coefficient (r) was calculated; $p < 0.05$ criterion was chosen for the determination of the reliability of relation.

RESULTS

Research allowed determining the values of internal and external factors affecting the values of competences possessed by security guards. For the analysis of security guards' internal evaluation factors (objectively depending on the abilities possessed by a security worker) appraised by experts (Figure 1), they were divided into three groups: 1) Very important (Theoretical and practical preparation (x_1) – 0.25; Mental qualities (x_3) – 0.21; Motor abilities (x_5) – 0.21); 2) Important (Fighting efficiency (x_6) – 0.16); Slightly important (Professional activity (x_2) – 0.09; Physical development (x_4) – 0.09). For the analysis of values of weights of security guards' external evaluation factors (subjectively depending on the appraisal given by the security guard's superior) (Figure 2), they were also divided into three groups: 1) Very important (Diligence and positive attitude to work (y_2) – 0.19; Reliability at work (y_4) – 0.17); 2) Important (Quality of work (y_5) – 0.14; Specialty knowledge, professionalism (y_1) – 0.13; Behaviour with colleagues and supervisors (y_3) – 0.13); 3) Slightly important (Image (y_7) – 0.08; Workload performance (y_6) – 0.07; Development rate (y_8) – 0.06; Being promising (y_9) – 0.03). Following the computation of correlations of factors evaluated by experts (Table 3), we determined factors having the greatest and the most frequent relations with other factors. These data allow us to determine universal factors reflecting generally the competences of a security guard. Appraisal of the security guards internal evaluation factors shows that Fighting efficiency (x_6) has the biggest number of reliable ($p < 0.05$) relations. However, this factor is negatively related with Theoretical and practical preparation (x_1) ($r = -0.511$), with Professional activity (x_2) ($r = -0.594$) and with Mental qualities (x_3) ($r = -0.594$). This indicates exceptional character and importance of this factor in the security guards' professional performance. Appraisal of the security guards' external evaluation factors provides dispersion of relations, with the dominance of negative relations. Image (y_7) and Quality of work (y_5) as well as Workload performance (y_6) and Being promising (y_9) are marked for the abundance of reliable ($p < 0.05$) relations with other

¹⁵ Sakalas A. *Personnel management*. Vilnius: Margi raštai. 2003.

¹⁶ Kendall, M. G. *Rank Correlation Methods, Fourth ed.*, Griffin, London, 1970.

expert evaluation factor indices. Analysis of relations between the indices of internal and external evaluation shows that Motor abilities (x_5) and Development rate (y_8) factors are marked ones.

DISCUSSION

With the globalization processes gaining speed all over the world, discussion about particular professional requirements to be met by people working in the private security sector are becoming more and more intensive¹⁷. A security guard accounts for the success of a private security, the quality of services offered, the clients' or other persons' confidence in private security structures and, most important, and the security of society¹⁸. Inquiry into the legislation of different states shows that most often the states provide only the minimum requirements (age, good health, basic training, and the absence of previous conviction record) for persons wishing to engage in the private security activities. Laws regulating the work of private security enterprises do not prescribe separately the requirements binding on a leading manager or a security guard of a private security. Private security enterprises have to create professional standards and employment procedures applicable to common and elite workers¹⁹. Research carried out by authors indicates that workers employed by private security enterprises ought to meet high requirements: the workers must be very knowledgeable about legislation, technology, physiology, etc., their physical and mental condition must be good, they must be given favourable conditions for the development and refreshment of acquired knowledge and skills which enables their adaptation to the ever-

changing requirements in the labour market²⁰. Research data allowed determining the values of weights of security guards' factors affecting their professional performance. Expert judgement ranked the factors as very important, important, and slightly important ones. However, inquiry into the correlation between expert judgements of the indices of examined factors revealed that factors with the greatest values of weights correlate with other factors poorly, and vice versa: factors with smaller values of weights are marked for a great abundance of correlations. This allows assuming that our research has covered only a part of factors affecting professional performance of security guards. Data on factors belonging to a very important group embrace unknown and undefined qualities of a security guard. Future inquiry into the competences possessed by security guards must analyse Theoretical and practical preparation (x_1), Mental qualities (x_3), Motor abilities (x_5), Diligence and positive attitude to work (y_2) and Reliability at work (y_4) in greater detail and look for their relations with other factors. It is possible to forecast that a system for the evaluation of security guards must be richer in terms of factors; this will enable to appraise their competences more objectively and precisely. It is necessary to develop new methods and systems for the evaluation and distribution of professional competences; these systems and methods must offer a chance to appraise factors which are hard to diagnose or yet unknown.

CONCLUSION

In Lithuania, like in many countries of the world, unified criteria for the security guards' evaluation are missing. The algorithm presented here provides landmarks in the creation of a comprehensive and thorough system for the security guards' evaluation. The research revealed the internal and external principles of security guards' evaluation. By values of weights, very important, important and slightly important factors affecting the professional performance of a security guard have been determined. The system developed for the security guards' evaluation

appraises unknown factors, so it is vital to increase the number of factors offered for evaluation and to evaluate their values of weights.

This will allow us to make the security staff evaluation procedure more efficacious.

Table 2. The expert judgment method (Kendall, 1970)

Determining criteria weights	r — number of experts, n — number of criteria considered, $j = \overline{1, n}$, $k = \overline{1, r}$; $r \geq 7$
Interviewing the highly skilled experts	t_{jk} — j^{th} criterion rank given by k^{th} expert
Sum of ranks for each criterion	$\bar{t}_j = \sum_{k=1}^r t_{jk}$
Average criterion rank	$\bar{t}_j = \frac{\sum_{k=1}^r t_{jk}}{r}$
Criterion weight	$w_j = \frac{\bar{t}_j}{\sum_{j=1}^n \bar{t}_j}$
Dispersion of experts ranking values	$\sigma^2 = \frac{1}{r-1} \sum_{k=1}^r (t_{jk} - \bar{t}_j)^2$
Variation	$\beta_j = \frac{\sigma}{\bar{t}_j}$
Ranking sum average	$V = \frac{1}{r} \sum_{j=1}^n \sum_{k=1}^r t_{jk}$
The total square ranking deviation	$S = \sum_{j=1}^n (\sum_{k=1}^r t_{jk} - V)^2$
The coefficient of concordance ($W \geq 0.5$)	$W = \frac{12S}{r^2(n^3 - n)}$
The significance of the concordance coefficient (no related ranks) $\chi_{\alpha, n}^2$	$\chi_{\alpha, n}^2 = \frac{12S}{rn(n+1) - \frac{1}{n-1} \sum_{k=1}^r T_k^2}$, where $\frac{1}{n-1} \sum_{k=1}^r T_k = 0$
Rank of table concordance χ_{tbl}^2 when the importance equal to 1%	The freedom degrees value of a solved problem $\nu = n - 1$; χ_{tbl}^2 = form statistical table
Compatibility of expert judgment	If $\chi_{\alpha, n}^2 > \chi_{tbl}^2$ — The hypothesis about the consent of experts in rankings is accepted
